A map of borrowing across diseases and outcomes

All eligible tuning tasks · patient-balanced within tasks · outcomes equally weighted within families

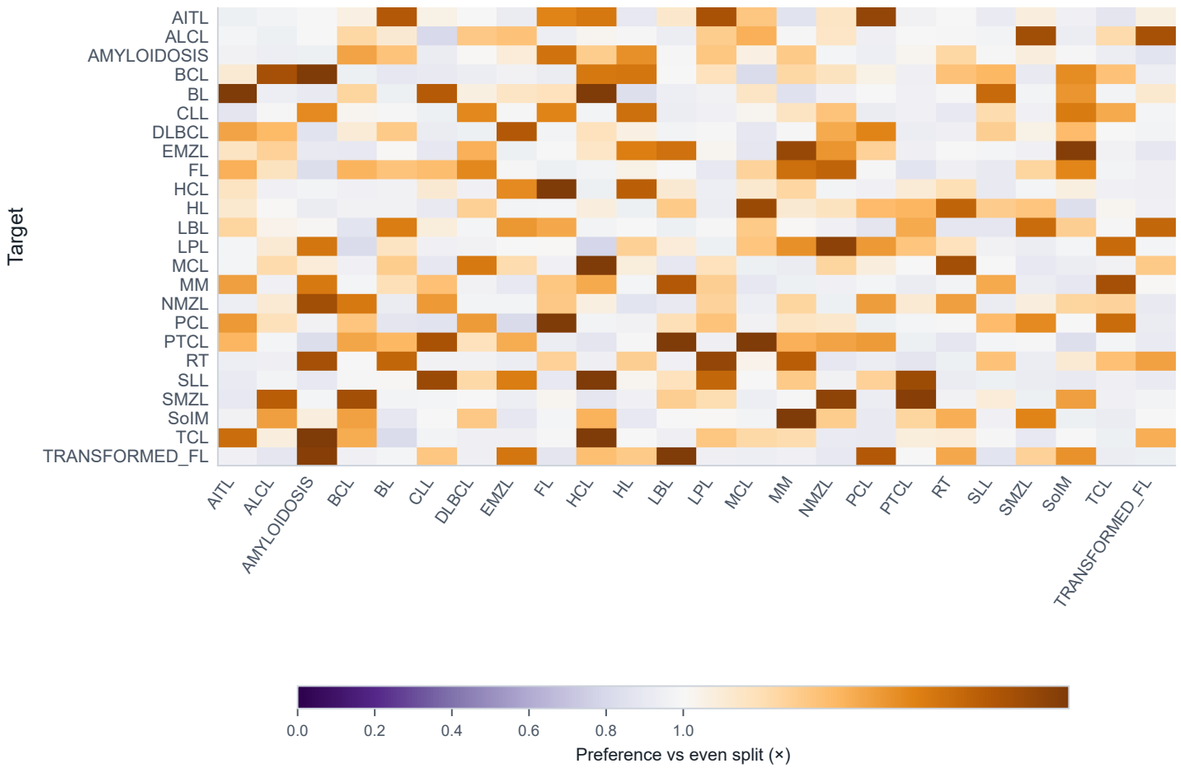

A Other-disease borrowing

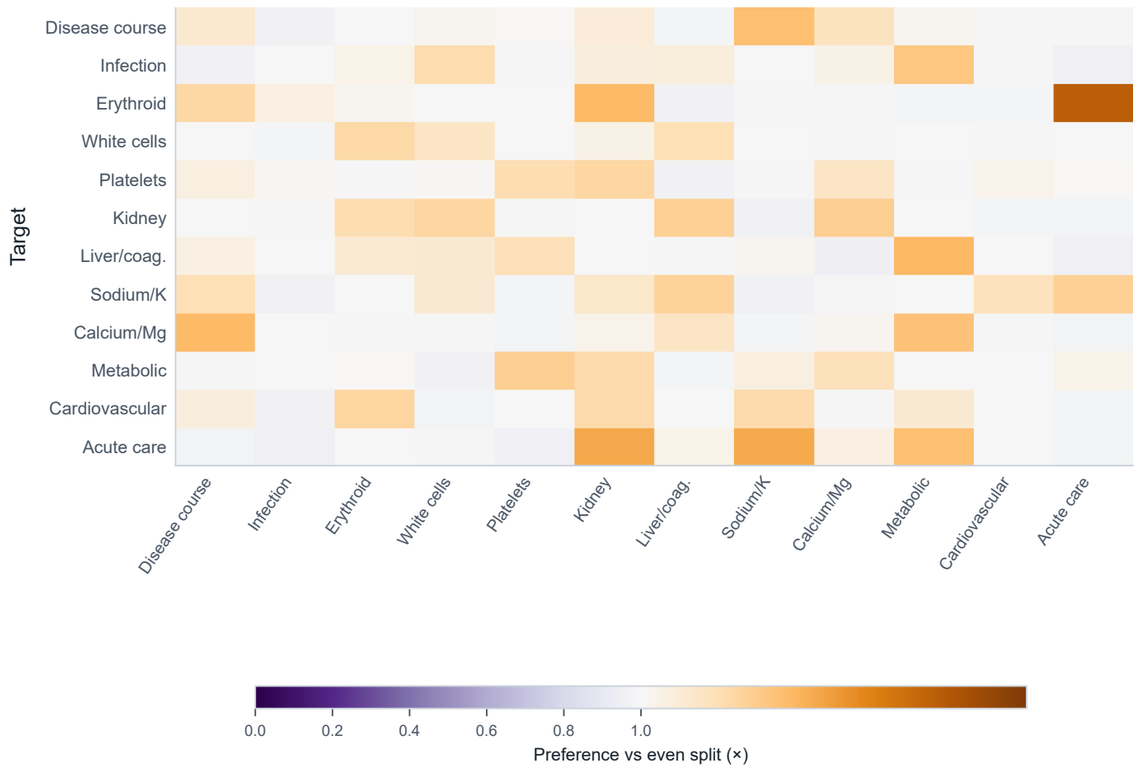

B Other-outcome borrowing

C Which diseases are preferred?

D Which outcome families are preferred?

A–B: total off-home gate mass; a larger outcome bank can have more total mass without selective routing. C–D: 1× means an even split within each bank; preference panels have separate scales.
Grey = insufficient tuning patients or a home source. Gate weight is not predictive benefit; outcome-family preference is per source adapter, not summed family mass.
